## AESTHACT

This thesis discusses the modification of an existing Optimal Systems Control FORTRAN Program (OPTSYS) originally obtained from Professor Arthur E. Bryson of Stanford University.

The modified FORTRAN program (OPTSYSX) is now designed to run completely interactively under VM/CMS on the IBM 3033 and is considered completely compatible with similar operating systems.

Program capabilities include: complete eigensystem analysis; the ability to perform computations on very large multivariate systems; controller, filter, regulator and compensator synthesis; transfer function analysis; steady-state gain determination; and nodal analysis.

The program permits users to rapidly carry out simulation, analysis, and design of all classes of Optimal Systems Control problems in a totally interactive mode. Examples of various types of problems are worked out during individual terminal sessions.

## SYMBOLS

A = state ( $N_s, N_s$ ) or output ( $N_o, N_o$ ) weighting matrix  
B = control ( $N_c, N_c$ ) weighting matrix  
C = control gain matrix ( $N_c, N_s$ )  
D = control ( $N_c, N_c$ ) or noise ( $N_o, N_g$ ) feedforward  
matrix  
E = expected value  
F = open-loop dynamics matrix ( $N_s, N_s$ )  
G = control distribution matrix ( $N_s, N_c$ )  
GAM = state disturbance distribution matrix ( $N_s, N_g$ )  
H = measurement scaling matrix ( $N_o, N_s$ )  
K = estimator gain matrix ( $N_s, N_{ob}$ )  
Nc = number of controls  
Ng = number of process noise sources  
Ns = number of states  
No = number of observations or measurements  
P = covariance matrix of estimate error ( $N_s, N_s$ )  
Q = white process noise covariance matrix ( $N_g, N_g$ )  
R = white meas. noise covariance matrix ( $N_o, N_o$ )  
S = steady-state covariance matrix of control ( $N_c, N_c$ )  
u = control vector ( $N_c, 1$ )  
v = white measurement noise vector ( $N_o, 1$ ), with  
zero mean and covariance matrix R  
w = white process noise vector ( $N_g, 1$ ), with  
zero mean and covariance matrix Q  
w0 = constant disturbance vector ( $N_g, 1$ )  
x = state vector ( $N_s, 1$ )  
xe = estimate of state vector ( $N_s, 1$ )  
y = output/measurement vector ( $N_o, 1$ )

#### ACKNOWLEDGEMENT

I would like to express my sincere appreciation to Professor L.J. Collins, whose assistance and encouragement contributed immeasurably to this research.

I wish to dedicate this thesis to my wife, Brenda. Without her constant love, support, and understanding this work would not have been possible.

## I. INTRODUCTION

The purpose of this thesis is to describe the extensive modification and improvement of an existing FORTRAN program (OPTSYS) used in the study, design, and application of Optimal Systems Control theory.

This optimal systems control program was originally developed by Hall [Ref. 1] in 1971 to support his research in rotary-wing VTOL aircraft control systems. The latest program modifications were made by Walker [Ref. 2] and Liu [Ref. 3] of Stanford University, to OPTSYS 4 and CPTSYS 5 respectively. These program versions performed quite satisfactorily in the batch environment, but exhibited varying degrees of user hostility due to data input format requirements and incomplete program documentation.

The original intent of this work was to adapt Walker's modified version of CPTSYS to run interactively under VM/CMS on the IBM 3033; however, the extensive modifications of OPTSYSX now represent a high-level interactive applications software system capable of integrated simulation, analysis, synthesis and design of broad classes of optimal systems control problems. With OPTSYSX users may now evaluate various specialized optimal systems control applications, relieved of the burden of lengthy mathematical program development.

It is assumed that the reader/user is familiar with the basic concepts of Control Theory and Optimal Systems Design. The problem descriptions and program development follow the terminology and symbol/naming conventions of Bryson [Ref. 4].

An explanation of the basic system of equations, the terms and symbolism used, and a program overview including the general methods of solution are presented first.

Interactive program development is then discussed, with an explanation of several alternate options available for data input.

This work concludes with examples of various types of problems demonstrated in the interactive mode, including a copy of each terminal session with the final results. A complete program listing is included in Appendix A.

## II. THE OPTSYSX COMPUTER PROGRAM

### A. INTRODUCTION

OPTSYSX is a double-precision FORTRAN program employing modern control theory analysis techniques. Although the program was originally written to synthesize controllers for rotary-wing VTOL aircraft [Ref. 5], it has been extensively modified to enable controller, filter, and regulator synthesis as well as transfer function and modal analysis on other types of large, multi-variable systems of equations. The program modifications described in this work now allow rapid numerical computer analysis in a completely interactive mode.

### E. SYSTEM/MODEL DESCRIPTION

OPTSYSX treats a linear stationary system model:

$$\dot{x} = [F]x + [G]u + [\text{GAMMA}]w \quad (2.1)$$

output equation

$$y = [H]x + [D]u \quad (2.2)$$

measurement equation

$$z = [H]x + [D]w + v \quad (2.3)$$

where

u = control vector ( $m \times 1$ )

v = white measurement noise vector ( $p \times 1$ )

w = white process noise vector ( $q \times 1$ )

x = state vector ( $n \times 1$ )

```

y = output vector (p X 1)
z = measurement vector (q X 1)

```

$[F]$  is the open-loop dynamics matrix (system matrix or plant matrix);  $[G]$  is the control distribution matrix;  $[\Gamma]$  is the process noise distribution matrix;  $[H]$  is the measurement distribution matrix; and  $[D]$  may represent a feed-forward distribution matrix of either the process noise vector ( $w$ ), or the control vector ( $u$ ).

The  $w$  vector has zero mean value, and a covariance matrix  $[Q]$ , where:

$$E(w) = 0 \quad (2.4)$$

and

$$[Q] = E[ww^T] \quad (2.5)$$

The  $v$  vector has zero mean value and a covariance matrix  $[R]$ , where:

$$E(v) = 0 \quad (2.6)$$

and

$$[R] = E[vv^T] \quad (2.7)$$

The quadratic performance (or cost) index for the linear quadratic regulator is the expected value of:

$$J = 1/2 \int \{y^T [A]y + u^T [B]u\} dt \quad (2.8)$$

in the statistical steady-state, where  $[A]$  represents an output cost matrix (a weighting on the output variables);

and  $[B]$  is a control cost (or control weighting coefficient) matrix.

If full state weighting is desired,  $[H]$  is represented by the identity matrix  $[I]$ .

## C. EECGFAM OUTPUT

### 1. Open-Loop Eicensystem Calculations

The initial portion of OPTSYSX output includes the program flow control flags set by the user for that particular run, the system of equations being modeled, and the open-loop eigenvalue and eigenvector calculations of the  $[F]$  matrix.

### 2. Regulator Synthesis Calculations

In the solution to the optimal regulator problem, full state variable feedback is assumed where:

$$[C] = [B^{-1}][G^T][S] \quad (2.9)$$

and

$$u = -[C]x \quad (2.10)$$

The control gain  $[C]$  is a matrix of optimal gains which minimize the cost index expressed in equation (2.8).

For optimal regulator synthesis problems, program output includes the closed-loop eigenvalues and eigenvectors; the control gain  $[C]$ ; the closed-loop dynamics matrix  $[F-GC]$ ; and the steady-state gain matrix  $[S]$ , where  $[S]$  is the steady-state solution to the algebraic Riccati equation:

$$S[F] + [F^T]S - S[G][B^{-1}][G^T]S + [H^T][A][H] = 0 \quad (2.11)$$

### 3. Filter Synthesis Calculations

A Kalman filter or Estimator which describes a continuous time system may be written as:

$$\dot{\hat{x}} = [F]\hat{x} + [K](z - [H]\hat{x}) \quad (2.12)$$

where:

$\hat{x}$  is the state estimate

$[K]$  is a matrix of filter gains,

and the state covariance is described by:

$$E(xx^T) = E(\hat{x}\hat{x}^T) + [P] \quad (2.13)$$

The filter gain matrix  $[K]$  of equation (2.12) is obtained from the relationship:

$$[K] = [P][H^T][R^{-1}] \quad (2.14)$$

where  $[F]$  is the steady-state solution to the algebraic Riccati equation:

$$[F]F + P[F^T] - P[F^T][R^{-1}][H]F + [G][Q][G^T] = 0 \quad (2.15)$$

representing the error covariance of the estimate  $\hat{x}$ . The control covariance is the expected value described by:

$$E(uu^T) = [C]\hat{x}[C^T] \quad (2.16)$$

For the Kalman filter/optimal estimator synthesis problem, CFTSYSX output includes the eigenvalues and eigenvectors of the optimal estimator (Kalman filter); the filter gains  $[K]$ ; the error covariance matrix  $[P]$ ; the covariance

matrix of the estimate  $\hat{X}$ ; the state covariance matrix  $[X]$  described in equation (2.13), where

$$[X] = E[XX^T] \quad (2.17)$$

and the control covariance matrix  $[U]$  described in equation (2.16).

#### 4. Stationary Closed-Loop Calculations

The stationary response of both state and control are presented as root-mean-square values of the state and control covariance matrices  $[X]$  and  $[U]$  described in equations (2.17) and (2.16) respectively.

#### E. SOLUTION ALGORITHM

One of the fundamental techniques necessary to quadratic synthesis of optimal control systems is the steady-state solution of the algebraic Riccati equation. This is a non-trivial task due to the iterative nature of the solution.

The steady-state solution by any quadrature method necessitates time increment selection no greater than some fraction of the shortest period of the closed-loop system; imposing a significant computer solution time expenditure on the user as well as the requiring an extensive amount of computer storage capability due to the matrix expansion factor involved. Further, the possible necessity of a time-varying solution of these equations for optimal open loop control or estimation requires the inversion of an  $n \times n$  matrix for each time increment where an unsteady solution is desired.

A powerful and efficient alternate method of solution was developed by Bryson and Hall [Ref. 7], based on eigenvector decomposition of the eigensystem of the constant coefficient EULER-LAGRANGE equations.

For the optimal regulator, these equations take the form:

$$\begin{bmatrix} \dot{x} \\ \dot{\lambda} \end{bmatrix} = \begin{bmatrix} F & G^T B^{-1} G \\ A & -F^T \end{bmatrix} \begin{bmatrix} x \\ \lambda \end{bmatrix}$$

For the optimal filter or estimator, the equations are of the form:

$$\begin{bmatrix} \dot{x} \\ \dot{\lambda} \end{bmatrix} = \begin{bmatrix} F & G \otimes Q \otimes G^T \\ H^T R^{-1} H & -F^T \end{bmatrix} \begin{bmatrix} x \\ \lambda \end{bmatrix}$$

CFTSYSX, and all earlier program versions, use the method of eigenvector decomposition of the EULER-LAGRANGE equations described in [Ref. 7] for quadratic synthesis of control systems. Program calculations are based on the QR algorithm of Francis, modified by Wilkinson [Ref. 8]. Important features of this method of eigensystem analysis are its improved accuracy, and its insensitivity to widely separated eigenvalues.

A more detailed description of the QR algorithm and its numerical applications to eigensystem analysis may be found in [Ref. 8].

## E. PROGRAM OVERVIEW

CFTSYSX and its 41 subroutines may be divided into three basic categories:

- 1) setup and computation sequencing
- 2) data input
- 3) calculation

A brief and general description of the program modules and subroutines supporting these basic categories concludes this section.

## 1. Problem Description/Program Flow Control

The MAIN program allows interactive selection of all program flow control flags, and is aided by three subroutines : RDREAL, RDINI, and RDCHAR. A detailed description of these subroutines is provided in Chapter III. Subroutine CHECK verifies the consistency of all requested program options.

## 2. Interactive Data Input

Interactive data input is performed by the 14 READ\_ subroutines. A detailed description of the operation of these subroutines is also included in Chapter III. Internal data generation or external data input is provided by subroutine SETUP.

## 3. Calculation Sequencing

Subroutine INNER functions as a second MAIN program. It orders the data input/calculation sequences for the type of problem being solved and performs numerous matrix calculations. It is from this subroutine that all input and calculation sequences are ordered and performed.

## 4. QR Algorithm Transformation

Subroutines MINV, BALANC, ORTHES, ORTRAN, HQF, HQF2, BALBAK, CNCRM, and ERExit perform the major calculation sequences of the "QR" algorithm.

## 5. Riccati Equation Calculations

Subroutine FGAIN separates the eigenvalues and eigenvectors of the Euler-Lagrange equations by eigenvector decomposition. RGAIN and subroutine SCOV calculate the steady-state solution of the Riccati equations for the controller or estimator problem. Subroutine SCOV computes

the covariance matrix solution to the algebraic Riccati equation.

#### 6. Modal Calculations

Subroutine MCDE computes the modal transformations required for modal analysis.

#### 7. Transfer Function Calculations

Subroutines TF, POLES, ZEROS, RESID, ACOMP, CCOMP, EQR, and Function SCI perform transfer function computations associated with Modal calculation sequences. Subroutine ESDCAI computes the power spectral density of the outputs or controls of a controlled system.

#### 8. Data Output

Subroutine RAERNT prints all program calculations in object time format. Subroutine MATPRT allows variable format screen viewing of all interactive matrix data input.

### III. INTERACTIVE PROGRAM OPERATION

#### **A. DESIGN CONSIDERATIONS**

During the development of CPTSYSX, all program modifications and additions were focused primarily toward interactive user operation. Experience has demonstrated that interactive computer communication offers many advantages in the research and problem solving environment. The opportunity for flexible and immediate computer communication, as well as the ability to select alternate solution methods, are significant advantages to the user; advantages which are unavailable in a batch processing environment.

Although previous versions of OPTSYS produced all the desired calculations in the batch environment, the input format and data sequencing and naming conventions were confusing to many users. The user was burdened with the necessity of verifying the correctness of input data format and program flow control flag settings for each program run, in order to ensure the desired calculation sequence was properly performed.

These requirements, combined with incomplete program documentation, prompted a lack of confidence in the results and discouraged many potential users from ever attempting to use CPTSYS.

#### **B. PROGRAM LANGUAGE**

CPTSYSX is programmed in FORTRAN IV, following the conventions of IBM System/360/370 FORTRAN IV language. Very few program features have been incorporated which are not written in ANSI Standard FORTRAN. These subtle differences notwithstanding, OPTSYSX has been compiled and run

under both FORTRAN IV (G1) and FORTRAN H (Extended) compilers on the IBM 3033. Although the overall program length is in excess of 2800 lines of text, it is considered completely portable from one operating system to another.

On the presumption that most scientific and research personnel are familiar with FORTRAN language, program modifications may be easily undertaken once system operation is understood.

### C. GENERAL PROGRAM MODIFICATIONS

All of the previously developed numerical calculation sequences of OPTSYS were retained un-modified in OPTSYSX.

Those program sequences requiring the input of diagonal cost or covariance matrix elements were deleted or modified to improve user flexibility in entering any desired weighting matrix, diagonal or otherwise. This modification streamlined program operation through elimination of several program flow control flags; reduced a measure of user uncertainty; and further decreased the required degree of user program familiarity--promoting uninterrupted operation.

The FEAD subroutines represent variations on the principle of simple, effective methods of interactive input, coupled with error-correction/recovery sequences.

Subroutines RDCHAR, RDINT, and RDREAL were developed by the author and Cdr. P.D. Sullivan to accomodate varying input format requirements; null-string entry protection was developed by Cdr. P.D. Sullivan. These program features are discussed in greater detail later in this chapter.

## E. INTERACTIVE PROGRAM DEVELOPMENT

### 1. Program Flow Control

Initial program development required an understanding of the various problem descriptions as well as program input and calculation sequence. After careful analysis of [Ref. 2], a basic program flow control diagram was established. From this flow control diagram, a logical branching network was formulated whose path could be determined through either binary logic or numerical selection.

Three basic branching categories were established from the various problem description statements:

Logical-----{"Yes" or "No"..."}

Integer-----{"1", "2", etc..."}

Real Number---{"Input the value of..."}

From the viewpoint of free-format computer communication, integer and real number input presented no significant problems. FORTRAN compiler language is written such that numerical data input (real number or integer) is expected, thereby requiring only an INTEGER or REAL data type statement within the program. Once the data type has been declared, the desired values may then be input with a free-format READ (5,\*) statement.

One note of caution concerning numerical data input in free-format deserves mentioning: Although all FORTRAN compilers treat character string input as an illegal data type conversion, many will automatically convert the inadvertent character entry to a "zero" and continue execution. Protection against inadvertent errors of this type is discussed later in this chapter.

Logical input ("Yes" or "No") poses a unique problem to programmers. The usual method of incorporation is to require the user to convert the logical answer into an integer i.e., "Yes" = 1, "No" = 2. These integers may then be read directly into the program, determining program flow.

Although this method may promote programming ease, it requires the user to adopt an unnatural habit pattern--one which increases the possibility of abnormal program termination in the event of inadvertent user error.

A more refined (from a programming language standpoint) and ergonomic (from the user viewpoint) method of logical selection involves utilization of the entire character string answer as an input value. This method has been incorporated into OPTSYSX.

The logical strings ("Yes" and "No") are declared as character strings in a data type statement within the program or subprogram. A format statement is also included in the program or subprogram utilizing the "A"-field to specify the desired character field width. A REWIND statement is then incorporated in the specific program or subprogram immediately prior to each logical string input point. This REWIND statement allows the input device (the terminal screen in this case) to read the character string in the same manner as free-format data input. The character field width for this modification was established at A1, allowing streamlined operation with the user typing either "Y" or "Yes" for an affirmative reply; "N" or "No" for a negative reply.

## 2. General Input Sequencing Requirements

All data input to OPTSYSX is in matrix or vector format. This data input must be correlated in accordance with the problem description and then properly sequenced in order for the program to perform the desired calculations.

The original and modified OPTSYS programs [Ref. 2] and [Ref. 3] required not only problem description knowledge but complete user familiarity with the detailed calculation sequence of the program. The latter point was considered a significant disadvantage. Elimination of this disadvantage

was an area where interactive programming offered the greatest benefits to the potential user; and it was toward this end that the remaining modifications of OPTSYSX were directed.

### 3. Interactive Data Input

In its calculation sequences, OPTSYSX requires the input of up to 14 unique matrices or vectors. Once the previously described program flow control diagram was constructed, data entry points for each matrix or vector were established. At each of the 16 program data entry points, the required input matrix or vector was determined. Fourteen input subroutines were added to the original program in order to accomodate interactive data entry.

These matrix input subroutines were written such that the user is first informed which specific matrix or vector is required; then prompted for the individual matrix element values. These values are then individually and sequentially entered from the terminal. Once the matrix or vector is filled, it is returned to the terminal screen for user verification and correction if necessary.

Interactive sequential data entry was programmed by means of a two-dimensional DO loop, with a terminal prompt of the matrix name and element position prior to the element value entry. Data element input is via a free-format READ (5,\*) program statement.

Once the matrix data entry sequence is complete, that input matrix is returned to the terminal screen in variable format for user ease in row identification. With an arbitrary data field width of 12 characters, the maximum number of matrix elements available on an 80 column terminal screen is six. Provided the matrix column dimension is less than six, this restriction presented no programming format limitations.

For those matrices whose column dimension exceeded six, elements were progressively written on subsequent terminal lines. Once the matrix row is filled the screen is double-spaced, and element display is repeated in the same fashion. This method allows the user to view the matrix much as he would expect to see it, providing the advantage of ease in row and column identification.

Within CPTSYSX, subroutine MATPRT performs this variable-format print sequence. The print sequence was arbitrarily terminated with a matrix size of 16 X 16, presuming that users with larger systems of equations would select alternate forms of data input.

#### 4. Saving Interactive Input

In most control system design problems, the system matrices generally remain relatively unchanged for a desired sequence of design calculations.

In order to relieve the user of the burden of repeated system entry in the interactive mode, several additional program flow control flags were added, allowing the option of saving the entire original system of matrices for subsequent calculations. Separate options for saving each system matrix are automatically offered at the end of each program run.

These matrix saving options provide a further advantage to the user in that the matrices are redisplayed for verification prior to calculation execution. Users may then change individual matrix elements, relieved of the burden of full system re-entry.

#### 5. User-Defined Input Files

Although the basic objective of this work is to provide the user with a totally interactive method of data input, several disadvantages to the method of individual

matrix element input are apparent--input of very large matrices is unwieldy and time-consuming; input of systems of matrices whose elements remain unchanged from run to run is inefficient.

In order to provide an increased measure of user flexibility in data input, subroutine SETUP was modified to include provisions for matrix data input from a data file on the user's disk. The three system matrices, [F], [G], and [GAMMA] may now be input from the user's disk. Minor program modification is required of the user as follows:

- a. FRICMS Filedef commands must be modified or added to reflect the name and location of each data set.
- b. The READ Format statement (or statements) must be changed to reflect the proper data format of the user's input file.

## 6. Internal Data Generation

As a further measure of flexibility, the documentation within subroutine SETUP was expanded to include several specific examples of internal matrix data generation. The three system matrices [F], [G], and [GAMMA] may be generated either within user-written two-dimensional DO-loops or by direct assignment statements. These methods may be preferable for the input of very large matrices with few non-zero elements.

A specific example of internal program generation of the output equation [H] matrix is included in subroutine READH. This matrix input method may be preferable for the entry of a large output equation matrix with very few non-zero elements.

Once these modifications have been made to subroutine SETUP or subroutine READH (as desired), the program should be re-compiled and then run in the usual manner. An

interactive program prompt is provided at the beginning of OPTSYSX offering the user the option of specifying the desired method of data input.

OPTSYSX was further modified to include the ability to input the [H] matrix (or other required input matrices) from separate data files. Users with rudimentary programming skills may now modify subroutine READH (or one of the other specific READ subroutines) in the manner previously described for subroutine SETUP or subroutine READH. Detailed examples of the nature and extent of these modifications may be found in Appendix A.

## 7. Data Entry Correction

In an effort to protect users from errors in data input, an error correction sequence was incorporated into each matrix input subroutine.

Once the entire matrix or vector is displayed on the terminal screen the user is prompted with the question, "Do you wish to change the value of any matrix element? Type 'Yes' or 'No'." If the user types "No", program execution continues.

If the user types "Yes", he is then prompted with three additional statements specifying the row number of the element to be changed, the column number of the element to be changed, and the value to be inserted into that matrix element. After the corrected value is entered, the new matrix values are returned to the screen for re-verification.

This correction sequence continues indefinitely until the user signifies that no additional changes are necessary. Program execution then proceeds normally.

## E. USER-ERROR PROTECTION FEATURES

Many interactive computer programs suffer the striking characteristic of abnormal program termination (without recovery!) should the user inadvertently make an erroneous keyboard entry. Examples of these inadvertent errors include--entry of a keyboard character or character string when the program expects a numerical value; entry of a numerical value when the program is expecting a character string; entry of a null string. In order to preclude abnormal program termination due to these types of inadvertent user errors, several program protection features were incorporated into OPTSYSX.

### 1. Data Type Conversion Errors

Three subroutines--RDREAL, RDINT, RDCHAR--were added to OPTSYSX in order to ensure that the proper input data type is provided to the program. Subroutine RDREAL is called at any point a real number or zero integer input may be encountered; subroutine RDINT is called at any point a non-zero integer input is required; subroutine RDCHAR is called at any point a character string ("Yes" or "No") input is required.

Within each of these subroutines a null string entry protection loop was incorporated (allowing one recovery); prompting the user for the correct data type input, and returning an error message in the event an incorrect data type is encountered.

Within subroutine RDINT, improper data type entry was further protected by the addition of a three-way IF comparison of entry integer magnitude. This modification precludes illegal (but automatic, with some compilers) data type conversion errors.

These program design features boast the additional advantage of allowing normal program termination at any point in the data input phase by merely pressing the "Enter" key twice.

## 2. Inconsistent Program Control Flag Errors

Earlier versions of OPTSYS [Ref. 2] and [Ref. 3], did provide user error messages in the event of inconsistent program flow control flags, but terminated the program. This feature was undesirable from the standpoint of smooth interactive program operation, and was improved in OPTSYSX.

Subroutine CHECK was modified to include RETURN statements any time inconsistent program flow control flags are encountered. The user is notified of the type of error encountered; that run termination has occurred; and prompted regarding his desire to return to the beginning of the program or terminate execution completely.

#### IV. PROGRAM USE AND EXAMPLES

This chapter contains several basic examples of the numerous types of problems which may be solved using CPTSYSX. Included with these examples are copies of each recorded terminal session.

Potential users should examine carefully the example of program failure found in Section D. This example clearly demonstrates that unstable modes or incorrect choice of certain design parameters may cause program failure (and incorrect output!), even with the highly stable "QR" algorithm. It also indicates one possible method of correcting this type of failure by merely making a very small change to one of the design parameters.

##### A. OPEN-LCCP EIGENSYSTEM ANALYSIS

The following open-loop eigenvalue example was taken from [Ref. 9, p.669].

Examination of the following program output shows open-loop eigenvalues at -1, -2, and -3. Note that the eigenvectors of the left and right eigenvector matrices (pa. 33) correspond in column fashion to the open-loop eigenvalues calculated immediately above them (pa. 32).

The full terminal session is recorded below, with user input in lower case letters following each "?" .

#### E. REGULATOR SYNTHESIS

The following regulator synthesis example was taken from "Lecture Notes on Advanced Control Systems", by Professor D.J. Collins of the Naval Postgraduate School, Monterey, Ca. This example involved determination of the optimal regulator gains based on an arbitrarily chosen quadratic index; with the various system and cost matrices described below.

Examination of the extensive program output indicates that the optimal regulator gains are: -5.0 and -SQRT(10.0). The algebraic sign of the gains is consistent with the definition displayed on the first screen of the program (p. 34).

The full terminal session is recorded below, with user input in lower case letters following each "?" .

### C. FILTER SYNTHESIS

The following Kalman filter synthesis example was taken from "Lecture Notes on Advanced Control Systems", by Professor D.J. Collins of the Naval Postgraduate School, Monterey, Ca.

This example involved determination of the optimal filter gains of an arbitrary system; modeled nearly identically to the previous regulator problem.

In its present configuration, OPTSYSX program sequencing requires the design of an optimal regulator, prior to performing any optimal estimator synthesis. In order to comply with built-in program sequencing conventions, and circumvent program difficulties which may not be specified in the particular system model, optimal filter synthesis may be accomplished by entering the identity matrix [I] in these

program input sequences requiring the entry of an output cost (weighting) matrix. Although the optimal regulator calculations may differ from those expected, the optimal estimator calculations will be correct for the system model.

Examination of the extensive program output indicates that the optimal filter gains are: -5.0, and -SQRT(2.0).

The full terminal session is recorded below, with user input in lower case letters following each "?" .

WILL A FEED-FORWARD DISTRIBUTION MATRIX  
"D" - MATRIX BE INPUT ?

TYPE "YES" OR "NO".

NO

THIS CPTION DETERMINES THE CRITERIA FOR DECIDING WHEN  
A MARKOV PARAMETER IS ZERO-THE MARKOV PARAMETER  
INDICATES THE COEF OF THE NUMERATOR POLYNOMIAL OF EACH  
TRANSFER FUNCTION.

ALL "N" ZEROS OF THIS POLYNOMIAL ARE PRINTED OUT AND  
THIS TEST TELLS HOW MANY EXTRA ROOTS EXIST AT Z = 0.  
LESS THAN 10.0\*\*(-IE) IS CONSIDERED ZERO.

THE DEFAULT VALUE OF THIS PARAMETER (IE) IS 6.  
IN OTHER WORDS, IE = 1.0E-6.

IF YOU DESIRE A DIFFERENT MARKOV CRITERIA,  
TYPE THE INTEGER VALUE.

IF YOU DESIRE THE DEFAULT VALUE, TYPE "0" (ZERO)

?

C

DO YOU DESIRE TO SYNTHESIZE A STABLE FILTER (OR REGULATOR)  
BY DESTABILIZING THE ORIGINAL SYSTEM?

(NOTE: WORKS FOR FILTER OR REGULATOR BUT NOT FOR BOTH  
IN THE SAME RUN.)

TYPE "YES" OR "NO".

NO

DO YOU DESIRE TO PRINT THE EULER-LAGRANGE EIGENSYSTEM  
STRUCTURE DECOMPOSITION (FOR CHECKING THE PROGRAM)?  
TYPE "YES" OR "NO".

NO

POWER SPECTRAL DENSITY (PSD) OPTION 1 :

OPTION 1 -- COMPUTE THE PSD OF THE OUTPUTS AND/OR  
THE CONTROLS OF THE CONTROLLED SYSTEM  
WHEN FORCED BY PROCESS AND MEASUREMENT  
NOISE. (NOTE: BOTH A REGULATOR AND A  
FILTER MUST BE RESIDENT IN THE PROGRAM  
TO USE THIS OPTION.)

OPTION 2 -- SAME AS OPTION 1 ABOVE BUT ONLY PRINT THE  
RESIDUES OF EACH TRANSFER FUNCTION  
USED IN THE PSD COMPUTATION.

OPTION 3 -- NOT DESIRED.

SELECT AN OPTION: 1, 2, OR 3.

END RECORDING OF TERMINAL SESSION

## E. EXAMPLE OF PROGRAM FAILURE

The following pathological example of program failure during regulator synthesis was taken from the Journal of Guidance and Control, Vol.3, No.2, pp.190-192, March-April 1980.

In this example, the choice of the quadratic index value was the factor prompting program instability; leading to eventual program failure in subroutine HQR2. The calculated regulator gains of -5.1, and -3.1 (pa. 63) are not correct!

With a 'slight' modification of the cost matrix from a previous value of 4.0000 to a new value of 4.0001, the program was run a second time. Failure did not occur on the second run, and the new calculations (pa. 68) indicate filter gains of -2.0, and a "small" residue of 3.19D-14 (essentially zero). These are the correct values.

This example points out one possible method of correcting certain program failure modes, should they occur during execution.

The full terminal session is recorded below, with user input in lower case letters following each "?" .

Following the program failure example, that portion of the repeated terminal output was deleted up to the point where program execution of the second run begins.

EXECUTION BEGINS...
OPTSYSX IS A COMPLETELY INTERACTIVE OPTIMAL SYSTEMS CONTROL
PROGRAM. IT WILL SOLVE NUMEROUS CONTROL PROBLEMS ON THE
FOLLOWING TYPES OF SYSTEMS CONTROL EQUATIONS:
```

XDOT = (F)\*X + (G)\*U + (GAM)\*(W+W0)  
MEASUREMENT EQUATION--  
Z = (H)\*X + (D)\*W + V  
REGULATOR PERFORMANCE INDEX--  
J = 1/2 \* INTEGRAL (Y \*(A)\*Y + U \*(B)\*U) DT  
STATE FEEDBACK GAIN DEFINITION--  
U = - (C) \*X

DO YOU WISH TO CONTINUE? TYPE "YES" OR "NO".

yes

--DATA ENTRY--

ALTECUGH OPTSYSX IS SPECIFICALLY DESIGNED TO READ ALL MATRIX DATA INTERACTIVELY, SEVERAL ALTERNATE METHODS ARE AVAILABLE TO USERS:

METHOD 1--THE "F", "G", AND "GAMMA" MATRICES MAY BE READ FROM SEPARATE DATA FILES.  
METHOD 2--THE "F", "G", AND "GAMMA" MATRICES MAY BE EXPLICITLY DEFINED WITHIN SUBROUTINE "SETUP".  
(NOTE: IN EITHER CASE, THE USER SHOULD OBTAIN A COPY OF THE PROGRAM LISTING AND EXAMINE THE EXAMPLES CONTAINED IN S/R "SETUP".)  
DO YOU WISH TO CONTINUE? TYPE "YES" OR "NO".

yes

DO YOU WISH TO INPUT THE "F", "G", AND "GAMMA" MATRICES FROM SUBROUTINE "SETUP" IAW THE METHOD DESCRIBED ON THE PREVIOUS SCREEN?  
TYPE "YES" OR "NO".

no

GENERAL OPTSYSX OPTIONS:  
OPTION 1 -- SYSTEM ANALYSIS WITHOUT OPEN-LOOP EIGENSYSTEM CALCULATIONS.  
OPTION 2 -- SYSTEM ANALYSIS WITH OPEN-LOOP EIGENSYSTEM CALCULATIONS.  
OPTION 3 -- OPEN-LOOP EIGENSYSTEM FOUND AND PROGRAM TERMINATES.  
("F"--MATRIX ENTRY FOLLOWS IMMEDIATELY.)

OPTION 4 -- MODAL DISTRIBUTION MATRICES COMPUTED  
WITHOUT FILTER OR REGULATOR SYNTHESIS  
OF STEADY-STATE ANALYSIS.

SELECT AN OPTION: 1, 2, 3, OR 4.

?  
2

DO YOU DESIRE RMS VALUES OF STATE AND CONTROL?  
TYPE "YES" OR "NO".

yes

CFTSYSX LQR/CLASSICAL OPTIONS:

OPTION 1 -- OPTIMAL FILTER AND/OR REGULATOR  
SYNTHESIS WITH NO EXTERNAL "C" OR "K"  
MATRIX INPUT.

OPTION 2 -- OPTIMAL FILTER AND/OR REGULATOR  
SYNTHESIS WITH EXTERNAL "C"  
MATRIX INPUT.

OPTION 3 -- OPTIMAL FILTER AND/OR REGULATOR  
SYNTHESIS WITH EXTERNAL "K"  
MATRIX INPUT.

OPTION 4 -- OPTIMAL FILTER AND/OR REGULATOR  
SYNTHESIS WITH EXTERNAL "C" AND "K"  
MATRIX INPUT.

SELECT AN OPTION: 1, 2, 3, OR 4.

?  
1

DO YOU WISH TO DETERMINE THE STEADY-STATE RESPONSE  
FOR A CONSTANT DISTURBANCE?  
TYPE "YES" OR "NO".

no

DO YOU WISH TO DETERMINE THE MODAL DISTRIBUTION  
AND GAIN MATRICES?  
TYPE "YES" OR "NO".

no

CPEN-LCOP TRANSFER FUNCTION OPTIONS:  
OPTION 1 -- NO CPEN-LCOP TRANSFER FUNCTIONS COMPUTED.

CPTION 2 -- POLES, RESIDUES, AND ZEROS COMPUTED.

CPTION 3 -- ONLY POLES AND ZEROS COMPUTED.

CPTION 4 -- ONLY POLES AND RESIDUES COMPUTED.

SELECT AN CPTION: 1, 2, 3, OR 4.

?

2

NCISE TRANSFER FUNCTION OPTIONS:

CPTION 1 -- NC NOISE TRANSFER FUNCTIONS COMPUTED.

CPTION 2 -- POLES, RESIDUES, AND ZEROS COMPUTED.

CPTION 3 -- ONLY POLES AND ZEROS COMPUTED.

CPTION 4 -- ONLY POLES AND RESIDUES COMPUTED.

SELECT AN CPTION: 1, 2, 3, OR 4.

?

1

COMPENSATOR TRANSFER FUNCTION OPTIONS:

CPTION 1 -- NC COMP. TRANSFER FUNCTIONS COMPUTED.

CPTION 2 -- POLES, RESIDUES, AND ZEROS COMPUTED.

CPTION 3 -- ONLY POLES AND ZEROS COMPUTED.

CPTION 4 -- ONLY POLES AND RESIDUES COMPUTED.

(NOTE: A COMPENSATOR TRANSFER FUNCTION CAN BE  
COMPUTED ONLY IF BOTH A REGULATOR  
AND FILTER ARE SYNTHESIZED  
AND/OR INPUT.)

SELECT AN CPTION: 1, 2, 3, OR 4.

?

1

WILL A FEED-FORWARD DISTRIBUTION MATRIX

("D" - MATRIX) BE INPUT?

TYPE "YES" OR "NO".

10

DO YOU DESIRE TO SYNTHESIZE A STABLE FILTER (OR REGULATOR)  
BY DESTABILIZING THE ORIGINAL SYSTEM?

(NOTE: WORKS FOR FILTER OR REGULATOR BUT NOT FOR BOTH  
IN THE SAME RUN.)

TYPE "YES" CR "NO".

NO

DO YOU DESIRE TO PRINT THE EULER-LAGRANGE EIGENSYSTEM  
PRIOR TO DECOMPOSITION (FOR CHECKING THE PROGRAM)?  
TYPE "YES" CR "NO".

NO

POWER SPECTRAL DENSITY (PSD) OPTION 1 :

OPTION 1 -- COMPUTE THE PSD OF THE OUTPUTS AND/OR THE  
CONTROLS OF THE CONTROLLED SYSTEM WHEN FORCED BY  
PROCESS AND MEASUREMENT NOISE. (NOTE: BOTH A  
REGULATOR AND A FILTER MUST BE RESIDENT IN THE  
PROGRAM TO USE THIS OPTION.)

OPTION 2 -- SAME AS OPTION 1 ABOVE BUT ONLY PRINT THE  
RESIDUES OF EACH TRANSFER FUNCTION  
USED IN THE PSD COMPUTATION.

OPTION 3 -- NOT DESIRED.

SELECT AN OPTION: 1, 2, OR 3.

?

3

DO YOU DESIRE REGULATOR SYNTHESIS ONLY?

## V. CONCLUSIONS AND RECOMMENDATIONS

### A. CONCLUSIONS

Although originally developed for the quadratic synthesis of controllers for rotary-wing VTOL aircraft, the extensive modifications and enhancements of Hall's original work, coupled with its efficient and accurate eigensystem solution routine, represent a powerful tool in the design of optimally controlled systems.

In its present interactive form, OPTSYSX has been transferred from the arena of high-level applied mathematics and numerical analysis to the level of control system engineers and students. It now represents an even more powerful educational tool, able to rapidly and effectively unlock many misunderstood linear systems mathematical relationships.

As an ultimate evaluation of the computational abilities of OPTSYSX, the program was tested using an 82 X 82 matrix of aircraft longitudinal motion equations for the VX-29 experimental Fighter aircraft derivative, provided by NASA-Fairchild.

For a system of equations of this magnitude, all program arrays were re-dimensioned (as shown in Appendix A), and a 2-Megabyte virtual machine size was required. This system was run through the Modal Analysis option of OPTSYSX, requiring less than 90 seconds to load the system and complete all open-loop and modal analysis calculations!

Program results exhibited perfect eigenvalue correlation with those obtained from the John Edwards Control Program. Additionally, OPTSYSX provided complete longitudinal modal analysis, previously unavailable on a system of this size.

It is hoped that the use of this interactive program version will be encouraged; and that its expanded abilities will stimulate both interest in and research on basic systems control problems, as well as more advanced designs.

## E. RECOMMENDATIONS

Based on the results of this thesis, four areas emerged as possibilities for further research and study:

### 1. Program Availability

The use of CPTSYSX and similar design programs should be encouraged in all undergraduate and graduate level courses involved in the analysis and design of control systems. Toward this end, it is recommended that CPTSYSX be placed in the non-IMSL library of subroutines, making it easily available to all potential users.

### 2. Computer Graphics

The addition of graphical plotting routines to the program in the time and frequency domain would make CPTSYSX an even more powerful tool in the design of many optimally controlled systems.

### 3. Further Modifications

The present version of the program should be modified to include the CPTSYS 5 derivative input term improvements of Liu [Ref. 3], and program sequencing during optimal filter synthesis should be examined. Various test runs indicate an area of conflict in that the program appears to require the design of an optimal regulator prior to performing any filter calculations.

#### 4. Program Application

CPTSYSX offers attractive possibilities in the area of microcomputer implementation.
